Installing Go and Goxpyriment to create your own experiments 1

Installing Go and Goxpyriment to create your own experiments

1. Install [Go](#) on your computer (if you are new to this, consult the [detailed instructions](#))
2. Either:

- Clone [goxpyriment Github repository](#), by opening a Terminal (App Git Bash under Windows), and executing the command-line

```
git clone https://github.com/chrplr/goxpyriment.git
```

Later, a simple `git pull` will suffice to upgrade goxpyriment to the latest version.

- Or download and unzip [main.zip](#).

3. On a command line in a Terminal, navigate to the goxpyriment folder and execute:

```
./build-all.sh
```

(Note: On Linux/macOS you can instead use `make all`)

This will compile the codes in [examples/*](#) and [test/*](#) (Note: The first time, this will take a while because Go needs to download several libraries. Once this is done, future compilations will be fast.)

After this operation, a new `_build` folder should contain many binaries (executable apps), that you can either run from the command line, or launch by clicking on their icon in a the file browser.

Program your own experiments

Once goxpyriment is installed, follow the step-by-step guide in [Creating Your Own Experiment](#), which walks you through writing, running, building, and sharing your own experiment. For background and reference, see [Getting Started](#), the examples' [source codes](#), and the [available functions](#).
